AB - J09285488 A stretchable composite sheet consists of a nonwoven fabric

being stretchable at least laterally with an elongation of 100% or higher and having an elastic sheet having a stretchability with an elongation of 400-800%, joined weakly in the central region or unjoined to form a stretch maintaining area and heat-fused entirely in the right and left end areas in the lateral direction to form non stretchable areas. Both areas are composed of the fabric and sheet alone in integrated form. The composite sheet permits formation of bonding parts in which a specified bonding part material is bonded to the end area while retaining the stretchability. Pref. the elastic sheet is an elastic film. Also claimed are: (i) a diaper side part material composed of the composite sheet: one end in the lateral direction is bonded to the diaper body, and an engaging part to the body is bonded to the other end; and (ii) production of the stretchable composite sheet comprising introducing a stretchable elastic sheet and a nonwoven fabric stretchable at least laterally, with the fabric superimposed on at least one side of the sheet, between a nip roll having convex parts on the peripheral surface at specified intervals in the width direction of the roll and a press roll consisting of a cooling roll opposite to the nip roll in order to join the sheet and fabric thermally at the convex parts of the nip roll in the longitudinal direction.

- USE - The composite sheet is used as side part materials for diapers and also available as a stretchable fixing part material for supports used in sports.

- ADVANTAGE - The composite sheet ensures stable connection and fixing and is easy to produce industrially with consistent quality.
